

## FOREWORD

---

Effective treatment of trophoblastic neoplasia and choriocarcinoma, became possible with the introduction of cycle-specific chemotherapy agents some 65years ago. This textbook is a remarkable collection of essays from first- and second-generation trophoblast canters, by the originators of this therapeutic revolution and by some of the second and third generation of physicians whom they trained. It is a significant multi-author endeavour to cover this fascinating field that combines genetic aberration and therapeutic pitfalls, which require both clinical skill and experience to achieve successful outcome.

The pathologic features and the discussion of the clinical manifestation of trophoblastic disease were steeped in controversy at the end of the nineteenth century. Now, early in the twenty first century, the knowledge concerning the genetic basis, the pathophysiology, the clinical categorization as well as the means of treating trophoblastic disease are much more firmly established and are all well described in this text. It is, therefore, remarkable that the diagnostic criteria and the methods of staging and assessment used in different canters as well as the way therapy is approached are still so widely divergent, and that in spite of the wealth of information opinion and practice are still so disparate. Hopefully, however, these writings will stimulate rigorous discussion that will permit wider consensus within the near future.

The shining spark of truth cometh forth only after the clash of differing opinions.
